Applet Fills Visible Portion Of Browser Window

Sample code for the system demonstrating this “How To” can be run from the “Applet Fills Visible Portion of Browser Window” section of:

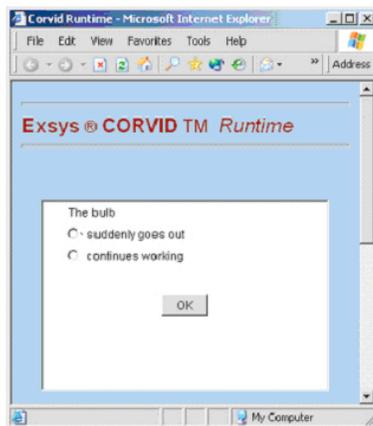

<http://www.exsys.com/support/howto>

The code for the sample system can be downloaded from the same page.

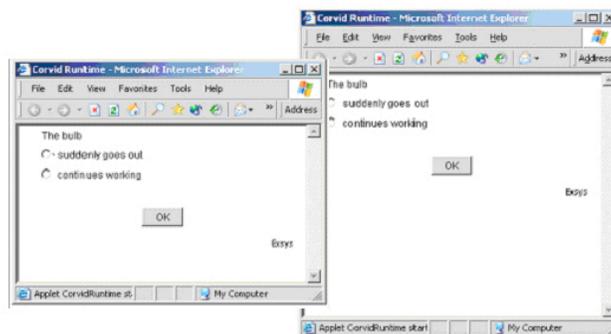

Normally the applet box used to run a Corvid system is a fixed size in a browser window, with other HTML content around it. For most systems this is preferred since the areas outside of the applet box can contain company logos, titles, instructions and any other information that is static, but which should be displayed with the application.

However, for some systems, it may be preferred to use a design where the applet box occupies the entire visible portion of the web page in the browser. This allows the applet box to fill the entire window and it is resized when the browser window is resized. This makes the border of the applet box no longer noticeable, and in many ways the systems looks more like it is running with the Corvid Servlet Runtime.

Normal Corvid display with Applet in a fixed section of an HTML page

Applet modified so that it fills the browser window, and can be resized with the window

How it Works:

To accomplish this effect, change the width and height of the APPLET tag in the HTML file from a fixed width and height to "100%".

You cannot type in "100%" for the Width and Height in the 'Applet Options' in the Corvid 'Properties' window because Corvid requires it to be a numeric, therefore you must edit the WIDTH and HEIGHT in the '.html' page, as shown below. Use Notepad or any text editor.

```
<APPLET
  CODEBASE = "."
  CODE = "Corvid.Runtime.class"
  NAME = "CorvidRuntime"
  ARCHIVE = "ExsysCorvid.jar"
  WIDTH = "100%"
  HEIGHT = "100%"
```

After setting the WIDTH and HEIGHT to "100%", the applet box still will not fill the entire visible portion of the browser window. This is because the <body> tag has margins (blank space) around it. This can be hidden using CSS. To turn off this margin, add <style> tags like this between the <head>...</head> tags:

```
<HTML>
<HEAD>
  <style type="text/css"><!--
  body {
    margin: 0;
  }
--></style>
</HEAD>
```

If you have an external '.css' file, you can add it there instead.

Lastly, in most systems, the KBWIDTH parameter should be deleted. This tells Corvid the width to use in wrapping text. Since the user can now set the width with their browser, the value should not be fixed unless this is required for a layout that you expect the user to set their browser to, or the applet is displayed in a "popup" window of a specific size. Delete the line in the applet tag:

```
<PARAM NAME = "KBWIDTH" VALUE = "700">
```

Corvid will then set the text wrap points based on the width the user sets.

Note: The applet will change the wrap points the next time the screen is redrawn. It will not "flow" to follow the resize until the user causes the screen to be redrawn.

Considerations:

This approach should only be used if the applet is used to display all graphics and information in a system. Many systems find it better to have static content outside of the applet.

The effect is lost if there is text above the <applet> tag, but an image or table can be acceptable if it occupies 100% of the width. Also, the HEIGHT does not have to also be "100%" allowing static content above and below the applet region.

If Internet Explorer is used to run the system locally during development, and it is set to block dynamic content such as applets, having the applet height at 100% will cause the IE to not display the message that allows you to select to run the system. This appears to be an IE "bug". It does not occur when running the system from a server.
